Osmosis describes the diffusion of the solvent through a semipermeable membrane. The driving force of the solvent shift is the concentration difference of solutes in the solutions separated by the semipermeable membrane. In contrast to solvent, solutes cannot pass this barrier.

Osmosis. Osmosis is a specific type of diffusion; it is the passage of water from a region of high water concentration through a semi-permeable membrane to a region of low water concentration. Semi-permeable membranes are very thin layers of material which allow some things to pass through them, but prevent other things from passing through. Cell membranes are an example of semi-permeable membranes.

Diffusion and Osmosis - Biology LibreTexts

However, diffusion is not the only natural force the cell has to contend with to stay alive. The other one, which affects the cell's ability to control its volume, is osmosis. Osmosis takes place when two solutions of different concentration are separated by a semi-permeable membrane in which the solvent can pass through but not the solute.

Diffusion and Osmosis: Twin Perils in the Life of the Cell ...

Mechanism of osmosis. Osmosis is a phenomenon of paramount significance for the transport of water and solutes through biological membranes. It accounts for fluid transport out of the kidney tubules and the gastrointestinal tract, into capillaries, and across cell membranes. The thermodynamic equations for osmosis are well established [1], but, despite the fundamental significance for biological fluid transport, an understanding of osmosis at the molecular level has been lacking.

Diffusion: Osmosis: Any type of substance moves from an area of highest energy or concentration to a region of lowest energy or concentration. Only water or another solvent moves from a region of high energy or concentration to a region of lower energy or concentration. Diffusion can occur in any medium, whether it is liquid, solid, or gas.

What Is the Difference Between Osmosis and Diffusion?

Osmosis is a comparatively slower process than diffusion, as the movement of molecules is slow due to the presence of the membrane. Examples. So, the next time you observe grapes that swell up with water, remember that this takes place due to osmosis. Grapes are said to be in a hypotonic medium when immersed in water.

Osmosis is a physicochemical process, in which the concentration difference between two solutions creates pressure difference (osmotic pressure) across a separating semipermeable membrane. See Article History. Osmosis, the spontaneous passage or diffusion of water or other solvents through a semipermeable membrane (one that blocks the passage of dissolved substances—i.e., solutes). The process, important in biology, was first thoroughly studied in 1877 by a German plant physiologist, Wilhelm Pfeffer.

Mechanism of osmosis. The phenomenon of osmosis may be observed by dividing a container into two equal volumes with a semipermeable membrane. As shown in Fig. 1, the left side contains pure water, the right side contains a dilute glucose solution, and the water levels are equal. Over time, the level on the right rises as water flows from the left to the right side.
