Microphone Arrays and Time Delay Estimation

The processing circuit for each microphone can employ an electronic time delay to compensate for the audio time delay of the microphones. Endfire microphone arrays are similar to broadside microphone arrays in that the signals from the desired direction sum in a constructive manner, but signals from directions other than the desired direction sum to a lower value.

The first element indicates the microphone with zero delay, used a time reference for the other microphones. This vector is called the array response vector, or manifold vector, but most usefully known as the steering vector, and represents how the array will respond to plane waves of frequency ω

incident along direction in 3D space.

It is easy to see that the direction from which a wave front originates has an effect on the time at which the signal meets each element in the array. When arriving from -45° the signal reaches the left hand microphone first, when arriving from perpendicular to the array (called broadside) the signal reaches each microphone at the same time and when from $+45^\circ$ the right hand microphone receives the signal first.

= 48 kHz, a 3-sample delay results in an acoustical time delay of about $63\mu\text{s}$. This is the time it takes sound to travel about 21 mm, which is the spacing between microphone elements for a cardioid pattern. The half-wavelength of an 8.2 kHz sound wave is 21 mm, so this is the null frequency. Figure 10

Microphone Array Beamforming - InvenSense

Phase is the degree line of reference for the time that a microphone begins recording, meaning, it determines the time that all microphones in an array start and stop recording. If microphones have drastically different phases, they will record signals at different times. This will lead to unsynchronized recording.

The delay-and-sum beamforming can also be implemented in the frequency domain. In the frequency domain, it can be achieved by applying a phase delay to the frequency spectrum of each array element, and then summing all the delayed spectrum, ie, [10.9]
$$e Z (\omega, x) = \sum_{m=0}^{M-1} w_m U_m (\omega, x) e^{-j \Delta \phi_m (\theta)}$$
 where $\Delta \phi (\theta)$ is the phased delay which can be obtained from the Eq. [10.5], $U_m (\omega, x)$ is the frequency spectrum for the m th array element, and $Z (\omega, x)$ is ...

In real-time listening enhancement applications, such as hearing aid signal processing, sounds must be processed with no more than a few milliseconds of delay to sound natural to the listener. Listening devices can achieve better performance with lower delay by using microphone arrays to filter acoustic signals in both space and time.
