MYC produces the transcription factor Myc, which dimerizes with Max and bind target DNA sequences or E-boxes (with the sequence 5'-CANNTG-3') to regulate transcription of genes involved in cell growth and proliferation.

MYC on the path to cancer

The Myc family was first established after discovery of homology between an oncogene carried by the Avian virus, Myelocytomatosis (v-myc) and a human gene over-expressed in various cancers, cellular Myc (c-Myc). [citation needed] Later, discovery of further homologous genes in humans led to the addition of n-Myc and l-Myc to the family of genes.

C-MYC Signaling Pathway - Creative Diagnostics

Introduction to the Myc family. The Myc family of human transcription factors was identified after discovering homology between an oncogene carried by the Avian virus, Myelocytomatosis (v-myc), and cellular Myc (c-Myc), a human gene that is often over-expressed in several cancers. Two further transcription factors, n-Myc and l-Myc, were later added to the family.

What you need to know about the oncogene c-MYC

The s-Myc is similar to c-Myc in its ability to induce apoptosis requiring caspase activation. However, s-Myc is distinct from c-Myc in that it has activity to suppress tumor growth and does not require wild-type p53 to induce apoptosis. These facts suggest differential regulation between s-Myc and c-Myc.

MYC is an oncogenic transcription factor that regulates a broad set of gene programs essential to growth, differentiation, and proliferation 3. Given the almost ubiquitous nature of MYC genomic targets, MYC expression is tightly regulated at the transcriptional, translational, and posttranslational level.
