T-Topology: This is used for older DDR routing as it is unable to handle the higher signal rates that were introduced with DDR3 and DDR4. T-Topology will route the clocks, command, and address signals in a branch fashion from the controller to the memory devices while directly connecting the data lines.

Routing Ddr4 Interfaces Quickly And Efficiently Cadence

When working with DDR3 and DDR4 routing, the fly-by topology begins with the controller, starts with Chip 0, and routes through Chip N—or the upper data bit. Routing occurs in order by byte lane numbers, and data byte lanes are routed on the same layer. Routing can be simplified by swapping data bits within a byte lane if needed.

DDR4 succeeded DDR3 as the next generation of synchronous DRAM (SDRAM) software. DDR4 offers several improvements over its predecessor, including faster download speed, higher DIMM capacities, enhanced data integrity and power efficiency, and overall improved performance. Compared with DDR3, the DDR4

PCB design consists of several physical changes. First, DDR4 has 288 pins as opposed to DDR3's 240, and each data pin can achieve transfer rates exceeding 2 Gbps.

Routing Ddr4 Interfaces Quickly And Efficiently Cadence Proper memory chip use and DIMM connector placement enables the best possible path for routing. DDR4 SDRAM requires shorter routes and proper spacing for peak timing and optimal signal

Routing Ddr4 Interfaces Quickly And Efficiently Cadence

DDR SDRAM technology has reached its 4th generation. The DDR4 SDRAM interface achieves a maximum data rate of 3.6Gbps per bit (i.e., clock rate of 1.8GHz). There are four key challenges in designing the placement and routing of DDR4 SDRAM interface with multi-Gigabit transmission.

DDR4 Routing Guidelines and Length and Spacing Rules. In PCB design, to achieve the optimum routing path, it requires both proper DIMM connector placement and proper memory chip use.

In general, DDR4 SDRAM requires shorter routes and the appropriate spacing for peak timing and optimal signal integrity. PCB designers should also employ pin swapping in the relevant signal groups.

As Cavium has enhanced its PCB design process, Munroe notes that when routing DDR4 designs, it's best to route signals spaced at 5X the line width for better noise/coupling immunity. "I get a true serpentine and all of the lengths I'm looking for. My rule of thumb: if the space is available, use it," he said.

23 When routing the data lanes, route the outer-most (that is, the longest lane) first, because this determines the amount of trace length to add on the inner data lanes. 24 Route all signals within a given byte lane on the same critical layer with the same via count. Assuming ECC is used, the DDR4 data bus consists of nine data byte lanes.
