Previous work for dry granular materials, such as , , , has demonstrated that a hierarchical discrete-continuum coupling model can be established by using grain-scale simulations to provide Gauss point stress update for finite element simulations in a fully implicit scheme. Nevertheless, the extension of this idea for partially or fully saturated porous media has not been explored, to the best knowledge of the authors.

The coupling between two dissimilar numerical methods presents a major challenge, especially in case of discrete-continuum coupling. The Arlequin approach provides a flexible framework and presents several advantages in comparison to alternative approaches.

A natural method for capturing localised size effect behaviour in large polycrystal boundary value problems is concurrent coupling of discrete dislocation plasticity (DDP) to the crystal plasticity finite element (CPFE) method, a continuum method that accounts for the crystal structure and homogenises the effect of crystallographic slip. A planar method for concurrent coupling of DDP to CPFE in a single crystal was developed in [8, 9].

The great scientific interest in computational mechanics has yielded numerous continuum methods (CMs) that can be used to model mechanical problems at the engineering scale. This chapter focuses on the choice of the appropriate CM to be coupled with discrete element method (DEM) for highly dynamic studies. The CMs are divided into two classes: grid-based methods and meshless methods.

This paper introduces a three-dimensional discrete element-finite difference coupling method, in which the discrete-continuum interactions are modeled in local coordinate systems where the force and displacement compatibilities between the coupled subdomains are considered. The method is validated using a model dynamic compaction test on sand.
