Grothendieck fibrations have played an important role in homotopy theory. Among others, they were used by Thomason to describe homotopy colimits

Grothendieck laid a new foundation for algebraic geometry by making intrinsic spaces ("spectra") and associated rings the primary objects of study. To that end he developed the theory of schemes , which can be informally thought of as topological spaces on which a commutative ring is associated to every open subset of the space.

The main result is to show how an extension map $U: T \rightarrow T_0$ can be viewed as a bundle, transforming base points (models of T_0 in any elementary topos S with nno) to bres (generalized spaces over S). More generally, for any localic groupoid G (i.e. groupoid internal to the category of locales, in the sense of section 5.3), there exists a Grothendieck topos $\text{Sh}(G)$ classifying G -principal bundles.
