i.CZE analytes move in the EOF but separate into bands because of differences in their electrophoretic mobilities, μ .
ii.Differences in μ make each analytic's overall migration velocity slightly different, and difference in migration velocity = separation.
iii. μ 's are roughly a function of analyte charge and frictional and size differences.

Zone electrophoresis (ZE) is the most widely used mode. It is fundamentally the simplest form of CE, mainly because the capillary is only filled with buffer. Separation occurs because solutes migrate in discrete zones and at different velocities and are separated solely based on differences in μ_{ep} .

Following electrophoresis, the separated antigens are reacted with specific antisera placed in troughs parallel to the electrophoretic migration and diffusion is allowed to occur. Antiserum present in the trough moves toward the antigen components resulting in the formation of separate precipitin lines in 18-24 hrs, each indicating reaction between individual proteins with its

antibody.

Key Difference – Capillary

Electrophoresis vs Gel Electrophoresis

Electrophoresis is a technique that is used to separate biomolecules based on the particle charge, particle size, and the particle shape. The migration of the molecule, known as electrophoretic mobility, depends on the type of polymer/gel used, its pore size, the voltage provided, running time and the surface to volume ratio.
