The effect of polychromatic UV and visible light on the radical properties of humic acid (HA) extracted from composted shells of walnut tree Juglans regia was investigated. The exposure of HA solutions 2 mg/ml in 0.01 M Na₂CO₃ at pH=10.8 to the light from a 150-W xenon lamp increases the signal amplitude of electron paramagnetic resonance (EPR).

Why do different solvents affect UV-vis spectroscopy?

Substituents alter the emitted wavelengths of these molecules by affecting the electron densities. Electron Withdrawing Groups (or EWGs) withdraw electron density, thereby making the arrangement more stable. The energy level of the orbital affected subsequently lowers, causing a typically-noticeable red shift in the maximum wavelength.

The ultraviolet (UV) spectra for isoselenazoles, benzisosenazoles, and benzisosenazol-3(2H)-ones are similar to their sulfur and tellurium analogues except for a slight bathochromic shift according to the heteroatom in the order S < Se < Te <1984CHEC(6)333, 2002ZNB1115>. The first, long-wavelength band at around 320–358 nm is associated with the electronic transition involving the nonbonded electrons of selenium.
