Heats Of Reaction Lab Answer Key - trumpetmaster.com

Enthalpy of a reaction is the amount of energy or heat absorbed or released in a reaction. If energy is required, this is a positive number and the reaction is endothermic (endo = in). If energy is released, this is a negative number and the reaction is exothermic (exo = out). Photosynthesis is an example of an endothermic chemical reaction.

The heats of reactions is determined by the formula $\Delta H_{rxn}^{\circ} = \sum n_p \Delta H_f^{\circ} - \sum n_r \Delta H_f^{\circ}$. The principle of Hess's law of heat summation is used to calculate the heats of reactions from the measured values of heats of formation and combustion.

It is evident that the reactions all began immediately, seeing as they were very

short, between a 90-120 seconds. This means that heat was being produced immediately and the lid was not on the calorimeter to keep the heat from escaping. Once again, the loss of heat would have resulted in a lower enthalpy value.

The ΔH° rxn is the standard heat of reaction or standard enthalpy of a reaction, and like ΔH also measures the

enthalpy of a reaction. However, $\Delta H^\circ_{\text{rxn}}$ takes place under "standard" conditions, meaning that the reaction takes place at 25° C and 1 atm. The benefit of a measuring ΔH under standard conditions lies in the ability to relate one value of ΔH° to another, since they occur under the same conditions.

There are times in the lab when we want to know how much heat is given off or absorbed during a reaction. Sometimes this can be determined quite easily experimentally by measuring temperature changes. However, there will be instances when this is not a straightforward task.

1) Rewrite the balanced chemical

equations for the three reactions carried out in lab. Beside each reaction, write the ΔH (per mole) you calculated for that reaction. This will determine your

accepted value of ΔH . 2) Manipulate the first two chemical equations so that they add up to give the third equation (Hess's Law).
