Lentiviral Vector Systems For Gene

Lentiviral vectors in gene therapy is a method by which genes can be inserted, modified, or deleted in organisms using lentivirus. Lentivirus are a family of viruses that are responsible for notable diseases like AIDS, which infect by inserting DNA into their host cells' genome. Many such viruses have been the basis of research using viruses in gene therapy, but the lentivirus is unique in its ability to infect non-dividing cells, and therefore has a wider range of potential applications. Lentiviral vector systems for constitutive gene expression

Recently, progress has been made in the development of vectors based on the lentivirus genus of retroviruses, which ironically includes a major human pathogen, human immunodeficiency virus (HIV). As these vector systems for clinical gene transfer are developed, it is important to understand the rationale behind their design and development.

Lentiviral transduction is one of the most effective delivery system for stable gene expression. Unlike the retroviral system,

the lentiviral integration is cell cycle independent. The genetic materials encoded by the lentivirus can be efficiently delivered into both dividing and nondividing cells.

In terms of vector design, 2nd and 3rd generation lentiviral systems provided by Addgene separate transfer, envelope, and packaging components of the virus onto different vectors. The transfer vector encodes the gene of interest and contains the sequences that will incorporate into the host cell genome, but cannot produce functional viral particles without the genes encoded in the envelope and packaging vectors.

Addgene: Lentiviral Guide

This vector is built using a lentivirus (e.g. HIV; most well characterized lentivirus) as the blueprint. The HIV genome is made up of 9 genes and every single gene is required to cause disease. To make the vector, scientists select 3 or 4 different genes from the blueprint of the viral genome.

Viral and Non-Viral Vectors| Lentiviral, Adenoviral & AAV

Lentiviral Vector. The development of safe and efficient gene delivery systems helps to develop effective clinical protocols. Lentiviruses, which belong to a subgroup of retrovirus family, have the ability to infect proliferating and quiescent cells. Vector systems based on the human immunodeficiency virus (HIV) or other lentiviruses have the potential to be important tools for clinical gene therapy.

Main article: Lentiviral vector in gene therapy Lentivirus is primarily a research tool used to introduce a gene product into in vitro systems or animal models. Large-scale collaborative efforts are underway to use lentiviruses to block the expression of a specific gene using RNA interference technology in high-

throughput formats.

In one of the early gene therapy trials in 1999 this led to the death of Jesse Gelsinger, who was treated using an adenoviral vector. [2] Some viral vectors, for instance gamma-retroviruses , insert their genomes at a seemingly random location on one of the host chromosomes , which can disturb the function of cellular genes and lead to cancer.
