As said before, every

meta-analysis model is in itself a multilevel model, so this association also has exciting implications for meta-analysts: we can treat our meta-analysis as a structural equation model, in which the pooled effect size we want to estimate is the latent (or unobserved) variable (Cheung 2015b, 2015a).

The process of performing meta-analytic structural equation modeling (MASEM) consists of two stages. First, correlation coefficients that have been gathered from studies have to be combined to obtain a pooled correlation matrix of

the variables of interest. Next, a structural equation model can be fitted on this pooled matrix.

In the correlation-based meta-analytic

structural equation modeling (cMASEM), the average sample correlation matrix is used to estimate the average population model. Using a simple mediation model, we illustrated that random effects covariation in population parameters can theoretically bias the path coefficient estimates and lead to nonnormal random effects distribution of the correlations.

2. Structural Equation Modeling based Meta-Analysis. SEM is a multivariate technique to fit and test hypothesized models. Let y be a $p \times 1$ vector of a sample of continuous data from a multivariate normal distribution where p is the number of observed variables. It is hypothesized that the model for the first and the second

moments are functions of θ , where θ is a vector of parameters that can be regression coefficients, error variances, factor loadings, and factor variances.

Many theories and hypotheses, however, are represented by models which contain multiple effect sizes and complex relations (e.g., indirect or contextual effects). The emerging field of meta-analytic structural equation modeling (MASEM) brings together meta-analysis and structural equation modeling to examine these models and test these hypotheses across studies.

About the authors This book explains how to employ MASEM, the combination of meta-analysis (MA) and structural equation modelling (SEM). It shows how by using MASEM, a single model can be tested to explain the relationships between a set of variables in several studies.

Only meta-analytic tools enable that, either by indirectly projecting shared covariance (e.g., Khazanov & Ruscio, 2016) or by using structural equation modeling to directly control for it (M. W.-L. Cheung & Chan, 2005; Jak, 2015). Thus, a
