This paper describes the development and performance optimization of a parallel computing infrastructure for an unstructured-mesh global model (GRIST; Global-to-Regional Integrated forecast SysTEM). The focus is on three major aspects that facilitate rapid iterative development, including parallel computing, index optimization and an efficient group I/O strategy.

Abstract. As a typical Gauss-Seidel method, the inherent strong data dependency of lower-upper symmetric Gauss-Seidel (LU-SGS) poses tough challenges for shared-memory parallelization. On early multi-core processors, the pipelined parallel LU-SGS approach achieves promising scalability. However, on emerging many-core processors such as Xeon Phi, experience from our in-house high-order CFD program show that the parallel efficiency drops dramatically to less than 25%.

The main disadvantage of parallel robots is their small workspace in comparison to serial arms of similar size. Furthermore, the manipulability of parallel robots is often poor in some regions of the (already small) workspace. Another problematic issue is

effective modeling of parallel robot dynamics, often needed for control algorithms.

A screw theory based method that is efficient in modeling full Jacobian matrix for parallel mechanisms is used here. Express the angular velocity of the moving platform with respect to the global coordinate system using a vector w , and the linear velocity of a point in the moving platform that is instantaneously coincident with the origin of the reference coordinate system using a vector v_p .

The input information is introduced as the inhibition times of individual oscillators, and the output information is coded in the number of activator maxima observed on a selected oscillator. We have used the Oregonator model to simulate the network time evolution and the evolutionary optimization to find the best network for the considered task.
