In both these techniques, the experimental data (dispersion patterns and distance restrains) are combined throughout different computational protocols to propose a structure model that is compatible with the data [1,2]. However, it would be desirable to perform similar protocols with other experiential methods, not just to compute a static structure, but to integrate new data to understand new mechanisms, dynamics, and functions.

There are a lot of experimental and computational techniques available to evaluate a drug's affinity towards its target, each with their own pros and cons. Isothermal titration calorimetry (ITC) measures the binding energy of unmodified interactors directly at physiological temperature but is costly both materials- and time-wise.

The experimental setup is performed for various HGM contents and the corresponding CSF specimens are manufactured by a three-step process designed for improving the dispersion of HGMs in the cement matrix. The effective thermal conductivity values of foams are measured by means of the transient plane source (TPS) technology . Then, the computational model involving the random distribution of HGMs in the cement matrix is established and validated by the experiment.

Current increase in interest in the domain formation in multicomponent membranes also stems from the experiments demonstrating liquid ordered-liquid disordered coexistence in mixtures of lipids and cholesterol and the success of several computational models in predicting their behavior. This review includes basic foundations on membrane model systems and experimental approaches

applied in the membrane research area, stressing on recent advances in the experimental and computational techniques.
