Spectral Analysis and Filter Theory in Applied Geophysics

In mathematics, spectral graph theory is the study of the properties of a graph in relationship to the characteristic polynomial, eigenvalues, and eigenvectors of matrices associated with the graph, such as its adjacency matrix or Laplacian matrix.. The adjacency matrix of a simple graph is a real

symmetric matrix and is therefore orthogonally diagonalizable; its eigenvalues are real algebraic ...

There is also a second method for reducing spectral noise. Start by taking a very long DFT, say 16,384 points. The resulting frequency spectrum is high resolution (8193 samples), but very noisy. A low-pass digital filter is then used to smooth the spectrum, reducing the noise at the expense of the resolution. For example, the simplest digital filter might average 64 adjacent samples in the original spectrum to produce each sample in the filtered spectrum.

Periodogram and filtering Interpretation of the periodogram The periodogram can be interpreted as an estimate of the power at the output of a filter tuned to f . Assume that, for a given f , we wish to design a filter $w(f) = w_0(f) \cdots w_{N-1}(f)$ whose output $X(f) = wH(f)x = \sum_{n=0}^{N-1} w_n(f)x(n)$

Window sequences for spectral analysis are either symmetric or 1-sample short of symmetric (called periodic, DFT-even, or DFT-symmetric: p. 52). For instance, a true symmetric sequence, with its maximum at a single center-point, is generated by the MATLAB function `hann(9,'symmetric')`.
