The reason why composite construction is often so good can be expressed in one simple way - concrete is good in compression and steel is good in tension. By joining the two materials together structurally these strengths can be exploited to result in a highly efficient and lightweight design. The reduced self weight of composite elements has a knock-on effect by reducing the forces in those elements supporting them, including the foundations.

Composite construction refers to two load-carrying structural members that are integrally connected and deflect as a single unit. For composite beams, the two load carrying members are the structural steel beam and the concrete on composite metal deck with the shear studs being the element that connects them.

Once again, the main objective of the test was to investigate the ultimate moment resistance and ductility of the composite girder. The structural steel used in the test was a high-strength steel HPS70W having a nominal yield stress of 482 MPa (70 ksi). The general layout and dimensions of composite plate girder G2 are shown in Figure 7.8. Similar to G1, the composite plate girder G2 had an overall length of 12,801 mm and a length between supports equal to 12,192 mm.
